

Azure Basic App Service Pricing

<https://gemini.google.com/app/60a6ce72c6442b1e>

User prompt: howmuch do I pay for an azure web app in basic tier for azure app service, what are all hour, daily or monthly charges?

Response: In Azure App Service, pricing is billed **per App Service Plan instance**, not per individual web app. This means you can host multiple web apps on a single Basic plan at no extra charge, provided they share the plan's allocated compute resources.

Azure calculates charges down to the second based on an hourly pay-as-you-go rate (standardized to a 730-hour month for monthly estimates). Rates differ significantly depending on whether you run **Linux** or **Windows** (due to OS licensing).

1. Base Compute Costs (Basic Tier)

SKU Size	Specifications (vCPU / RAM / Storage)	Hourly Rate (Windows)	Monthly Cost (Windows)	Hourly Rate (Linux)	Monthly Cost (Linux)
B1	1 vCPU / 1.75 GB RAM / 10 GB Storage	~\$0.075 / hr	~\$54.75	~\$0.018 / hr	~\$13.00
B2	2 vCPUs / 3.50 GB RAM / 10 GB Storage	~\$0.150 / hr	~\$109.50	~\$0.036 / hr	~\$26.00
B3	4 vCPUs / 7.00 GB RAM / 10 GB Storage	~\$0.300 / hr	~\$219.00	~\$0.072 / hr	~\$52.00

Daily costs are simply 1 / 30th of the monthly estimate (e.g., ~\$1.82/day for a Windows B1 or ~\$0.43/day for a Linux B1).

2. All Potential Additional Charges

While the App Service Plan fee covers compute and the included 10 GB disk storage, your actual bill may include ancillary infrastructure charges:

- **Outbound Data Transfer (Egress):**
 - Inbound data transfer is **free**.
 - Outbound traffic: First **100 GB/month** is free. Beyond 100 GB, standard Azure egress rates apply (~\$0.087 per GB).
- **Manual Scale Out:**

- The Basic tier allows manual scaling up to **3 instances**. If you scale B1 from 1 instance to 2 instances, your hourly rate doubles (e.g., $2 \times \$0.075/\text{hr} = \$0.15/\text{hr}$ for Windows). (*Note: Basic tier does not support automatic scaling; autoscaling starts at the Standard tier.*)
- **Custom Domain & SSL Certificates:**
 - Custom domain bindings and custom **SNI SSL certificates** are **free**.
 - Optional **IP-Based SSL** incurs an additional fee (~\$193.62/month).
 - If you purchase a domain directly via Azure App Service Domains, it is billed as a yearly flat fee (~\$12–\$15/year depending on the TLD).
- **Custom Custom Container Image Registry Traffic:**
 - If your Basic App Service pulls custom Linux container images from Azure Container Registry (ACR), standard ACR storage/pull fees apply.
- **Database & External Services:**
 - Databases (Azure SQL Database, Azure Cosmos DB), Key Vaults, and Application Insights for telemetry are separate resources billed on their own respective meters.

User prompt: I created my web app initially with free tier and it failed with error 503 (with frequent messages of quota exceeded) then i upgraded to basic tier with b1 and I also received and I am receiving 503 error messages. I also had problems in instante status and I did 3 things: 1) restart service. 2) repair in the same instance and 3) repair with newinstance and the failure continue with 503 messages, Should I wait or delete and create a new(similar or equivalent resource) resource to solve the problem without having charges for a day or two?

Response: Deleting and recreating the resource is generally not necessary, and waiting alone will likely not resolve the issue.

The 503 error after upgrading from Free to Basic (B1) indicates that the problem is no longer an Azure quota block, but an underlying application startup or runtime crash. Recreating the exact same resource will usually produce the exact same 503 error if the application code or configuration is causing the failure.

Why 503 is Occurring on Basic (B1)

When you were on the **Free tier**, the 503 error was caused by reaching the **Daily CPU Quota (60 CPU minutes/day)**. Once exceeded, Azure's front-end load balancer automatically blocks requests with a 503 error until the quota resets.

When you upgraded to **Basic (B1)**, the CPU quota restriction was removed, but a persistent 503 error on B1 stems from a different root cause:

1. **Application Process Crash on Startup:** The web application code is throwing an unhandled exception or missing an environment variable, causing the runtime process (e.g., Node, Python, .NET Core) to crash repeatedly upon initialization.
2. **Port Binding Mismatch (Linux):** On Linux App Service instances, if the application does not listen on the default port exposed by Azure (or port specified by `WEBSITES_PORT`), Azure's container proxy will return a 503.
3. **Database or External Dependency Timeout:** If your app connects to a database (e.g., Azure SQL, MySQL) on startup and the connection fails or times out, the web process exits before it can serve requests.

Deleting vs. Troubleshooting: Cost & Action Plan

1. What happens if you delete and recreate?

- **Charges:** Azure App Service is billed per second based on the active App Service Plan instance. If you delete the App Service Plan now, billing stops immediately. Recreating a new B1 instance will only charge you for the exact hours/minutes it runs (a B1 Linux instance is ~\$0.018/hr; B1 Windows is ~\$0.075/hr). The cost for 1-2 days on B1 ranges from ~\$0.80 (Linux) to ~\$3.60 (Windows).
- **Effectiveness:** Creating a brand-new App Service won't fix the 503 if the application deployment package contains runtime errors or bad configuration settings.

2. Recommended Troubleshooting Steps (Before Deleting)

Instead of deleting the resource, diagnose the application logs directly from the Azure Portal or Azure CLI:

1. Check Application Event Logs / Log Stream:

- In the Azure Portal, go to your Web App → **Log Stream** (under *Monitoring*).
- If logs are disabled, go to **App Service Logs**, enable **Application Logging (Filesystem)**, save, and reopen **Log Stream**.
- Restart the App Service and observe the startup log output to locate uncaught exceptions or missing modules/settings.

2. Use "Diagnose and Solve Problems":

- Go to your Web App → **Diagnose and solve problems** (left menu).
- Select **Web App Down** or **Availability and Performance**. Azure's automated diagnostics will show if the worker process is crashing (*Application Crash*) or if container port mapping failed.

3. **Verify Environment Variables / App Settings:**

- Go to **Configuration** → **Application settings**.
- Confirm that all required connection strings, keys, or startup commands (`WEBSITES_PORT`, `SCM_DO_BUILD_DURING_DEPLOYMENT`, etc.) are configured.

Decision Matrix

Option	Cost Impact	Resolution Likelihood	Next Step
Wait	Incurs hourly B1 charges while idle	Low (a crashing application process will not self-heal)	Inspect Log Stream for startup crashes.
Diagnose Current App	Minimum hourly cost (~\$0.018–\$0.075/hr)	High (pinpoints exact application/config error)	Use Azure Log Stream or Diagnose and solve problems tool.
Delete & Recreate	Stops billing immediately upon deletion	Low (recreates empty app, but re-deploying same code yields same error)	Delete only if you suspect an Azure platform-level provisioning state corruption.
